**Parenteral Nutrition (PN):**

**Venous access**

### Intravascular catheters: choice and insertion

#### Types of catheter
- In newborns and children, peripherally inserted central catheters (PICC) and tunneled central venous catheters (CVC) should be used for administration of prolonged PN during hospitalization
- In children requiring long-term PN and home PN, a tunnelled CVC is recommended
- Catheter dedicated only to PN should be used
- A catheter with the minimal number of ports or lumens should be used
- If a multi-lumen CVC is in place, dedicate one lumen to PN; blood sampling, transfusion and central venous pressure monitoring from the CVC should be avoided
- To improve quality of life for patients on long term PN, blood sampling via CVC for routine monitoring is recommended, provided full aseptic protocol is followed

#### Catheter material
- Catheters used for long-term PN should preferably be made of silicone or polyurethane
- Antimicrobial coated CVC should not be used for children on long-term PN

#### Insertion sites
- In infants and children in whom CVC cannot be placed in superior vena cava, an option of femoral vein or subclavian catheter insertion can be recommended
- In newborns, umbilical vessels can be used for short term PN

#### Positioning of the catheter tip
- The CVC tip should lie outside the pericardial sac to avoid the risk of pericardial effusion/tamponade
- In small infants (body length 47-57 cm) the catheter tip of a jugular or subclavian CVC should lie at least 0.5 cm above the carina on a chest x-ray, while in older/larger infants (body length 58-108 cm) that distance should be at least 1.0 cm
- The catheter tip of a femoral catheter should lie above the renal veins (first lumbar vertebra)

#### Methods of insertion
- A percutaneous, radiologically or ultrasound guided insertion method may be used since this is equally effective as a surgical cut-down, and carries less risk of complications
Antibiotics prior to CVC insertion and routine catheter exchange

- CVC shall not be changed routinely in order to reduce the risk of sepsis
- If a CVC requires removal, replacement rather than exchange over a guidewire decreases the risk of infection. CVC exchange may be reserved for those patients with difficult venous access
- Prophylactic antibiotics do not reduce the risk of catheter related bloodstream infection, therefore they should not be administered

CVC locks and flushes

- Taurolidine is effective in preventing CRBSI and should be used during long term catheter use
- Ethanol line locks may be considered for preventing CRBSI
- Antibiotic line locks can be used in conjunction with systemic antibiotics to assist in the eradication of CRBSI in some patients
- Antibiotic line locks should not be used for treating CRBSI as these have not been shown to be effective

Hygiene and antisepsis on CVC insertion and during subsequent care

- Appropriate hygiene procedures should be followed before accessing the intravascular device or the insertion site
- Before insertion of an intravascular device and for post-insertion site care, clean skin should be disinfected with 2% chlorhexidine solution in 70% isopropyl alcohol
- Antiseptic solution should remain on the insertion site and be allowed to air dry before catheter insertion or dressing application
- Due to potential side effects, skin antisepsis with chlorhexidine in infants younger than two months cannot be recommended
- Catheter connectors, ports and hubs should be disinfected before accessing, preferably with 2% chlorhexidine solution in 70% isopropyl alcohol
Interventions to reduce CVC infection

**Dressing methods**

- Both sterile gauze with tape and transparent semi-permeable polyurethane dressing can be used to cover the catheter insertion site.
- Sterile gauze dressing is preferable if the catheter site is bleeding or oozing.
- For short-term CVC, site dressings should be replaced every 2 days for gauze dressing, and every 7 days for transparent dressing.
- A dressing should be changed sooner if it becomes damp, loosened or soiled.
- A tunnelled CVC with a well-healed exit site does not require dressing to prevent dislodgement, however, in children it is useful to have them looped and covered.
- Chlorhexidine-impregnated dressing should be considered in patients older than two months with short-term catheters who are at high risk for infection.
- Topical antimicrobial treatment at the insertion site cannot be routinely used as it may promote fungal infection, antimicrobial resistance and damage the surface of the catheter.
- Children with well-healed tunnelled catheters may be allowed to swim, provided that a water-resistant dressing is used to cover the whole catheter. Immediately after swimming the catheter exit site should be cleaned and disinfected, and the dressing changed.

**Multimodal strategies for prevention of CVC-related Complications**

- Regular training and education of healthcare staff with respect to catheter insertion and maintenance should be recommended.
- Multimodal protocols for healthcare providers, aiming to standardize clinical practice on insertion and maintenance of intravascular devices, should be developed and regularly audited.
